Previous ¹	Our Study
Low Frequency (Daily)	High Frequency (5-minute)
Simple architecture	Recurrent Neural Network
Price	Price and volume
Simple data processing	Sophisticated feature engineering
Offline learning	Online learning

- Minute-level US equity pricing and volume data since 2000, collected using Google Finance API. Processed with five-minute window.
- 50 largest stocks as ranked by market capitalization.
- Stocks are correlated, so we will use 600 dimensional lagged stock returns (50 stocks and 12 lagged returns) as raw level input data.

¹According to a survey on the previous researches of stock price prediction [1].

Our model follows the research of Chong et al.[2]:

$$\mathbf{r}_t = [r_1, r_2, \dots, r_{50}]$$

$$\mathbf{R}_t = [\mathbf{r}_t, \mathbf{r}_{t-1}, \dots, \mathbf{r}_{t-12}]^T$$

$$\mathbf{r}_{t+1} = f \circ \phi(\mathbf{R}_t)$$

ϕ :

- Data \rightarrow Features, e.g. mean, variance, etc.
- PCA, autoencoder, RBM, and other unsupervised learning techniques.

f :

- Predictor function.
- Recurrent Neural Network (RNN), state of the art for financial time series data analysis [3].

- **Measurements:** normalized mean squared error, mean absolute error, root mean squared error, and mutual information.
- **Bootstrap analysis:** will be performed on assessment of the accuracy of the estimator by random resampling with replacement from the original dataset.
- **Sensitivity:** of the result with respect to each feature and each stock will also be analyzed.

We believe an accurate prediction for stock price will lay a solid ground for a successful trading strategy. It will also shed light on the research of economics, finance, behavioral science, and mathematics.

These slides are modified from maminian's template[4].
